

CS-202

C++ Classes – Inheritance (Pt.1)

C. Papachristos

Autonomous Robots Lab
University of Nevada, Reno

Course Week

Course , Projects , Labs:

Monday	Tuesday	Wednesday	Thursday	Friday
			Lab (8:00-12:00)	
	CLASS		CLASS	
PASS Session	PASS Session	Project DEADLINE	NEW Project	

Your 5th Project will be announced today Thursday 10/5.

4th Project Deadline was this Wednesday 10/4.

- NO Project accepted past the 24-hrs delayed extension (@ 20% grade penalty).
- Send what you have in time!
- Check out **WebCampus** CS-202 Announcements for some **help** !

Today's Topics

Class / Object Relationships

- Inheritance
- Composition
- Aggregation

Inheritance Concepts & Practice

Class Hierarchy

Method Overriding

Inheritance Rules

Inheritance

Code Reuse

Important to successful coding

- Efficiency: No need to reinvent the wheel.
- Error free: If code already used/tested (not guaranteed, but more likely).

Ways to reuse code?

- Functions
- Classes
- Aggregation:
RentalAgency “has-a” *RentalCar*
- Inheritance!

Object Relationships

“*Uses d*” relationship:

- *ObjectA* “*uses an*” *ObjectB*
Car refuels from a *GasStation*

“*Has d*” – Composition or Aggregation

- *ObjectA* “*has an*” *ObjectB*
Car incorporates a *Sensor*

“*Is d*” or “*Is a kind of*” – Inheritance

- *ObjectA* “*is d*” *ObjectB*
Car is a *Vehicle*

Inheritance Relationship

What is Inheritance?

- A *Car* “is a” *Vehicle*

Code reuse by sharing related Set-Methods:

- Specific classes “Inherit” methods from general classes.

The *Car* Class Inherits from the *Vehicle* Class:

- *Vehicle* is the general class, or the *Base* Class.
- *Car* is the specialized class, or *Derived* Class, that Inherits from *Vehicle*.

Inheritance

Inheritance Relationship

Inheritance Example:

- Every *D* is a *B*
- Not every *D_i* is a *D_j*
- Some *B*s are *D*s

Derived
Class(es)

Inheritance

Inheritance Relationship

Inheritance Syntax:

```
class BaseClass {  
    public:  
        //operations  
    private:  
        //data  
};
```

Indicates that this *DerivedClass*
Inherits data and operations from
this *BaseClass*

```
class DerivedClass : public BaseClass {  
    public:  
        //operations  
    private:  
        //data  
};
```

Base Class

University_Member

Name

Address

Derived
Class(es)

Student

Major

GPA

Faculty

Research Area

Advisees

Inheritance

Inheritance Relationship

Indicative Code example:

```
class Vehicle {  
    public:  
        // functions  
    private:  
        // data  
    int    m_numAxles;  
    int    m_numWheels;  
    int    m_maxSpeed;  
    double m_weight;  
} ;
```

All *Vehicles* have
axles, wheels, a max
speed, and a weight

Base
Class

Derived
Class

Inheritance

Inheritance Relationship

Indicative Code example:

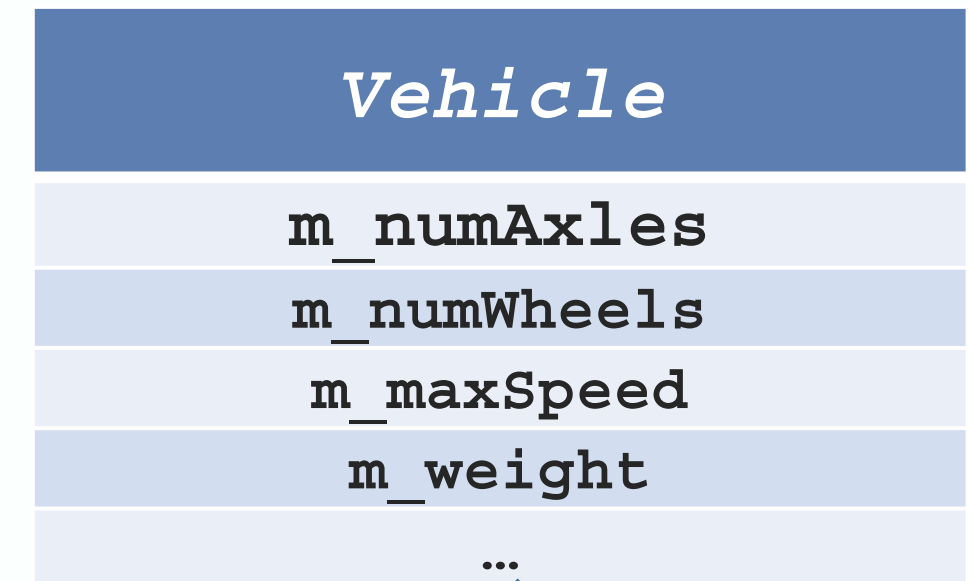

➤ Colon in Declaration indicates Inheritance.

```
class Car: public Vehicle {  
    public:  
        // functions  
    private:  
        // data  
    int     m_numSeats;  
    double  m_MPG;  
    string  m_color;  
    string  m_fuelType;  
} ;
```

All *Cars* have a number of seats, a MPG value, a color, and a fuel type

Base
Class

Derived
Class

Inheritance

Inheritance Relationship

Indicative Relationship Code:

```
class Car[:  
    public Vehicle { /*etc*/ };  
class Plane[:  
    public Vehicle { /*etc*/ };  
class SpaceShuttle[:  
    public Vehicle { /*etc*/ };  
class BigRig[:  
    public Vehicle { /*etc*/ };
```

Composition

Composition Relationship

What is Composition?

- A **Car** “*is made of a/ incorporates a*” **Chassis**

The **Car** Class contains a Class Object of type **Chassis**.

A **Chassis** Object is part of the **Car** Class:

- A **Chassis** cannot “live” out of context of a **Car**.
- If the **Car** is destroyed, the **Chassis** is also destroyed!

Composition

Composition Relationship

Indicative Code example:

➤ No Inheritance for *Chassis*:

```
class Chassis {  
    public:  
        // functions  
    private:  
        // data  
    char m_material[MAT_LENGTH];  
    double m_weight;  
    double m_maxLoad;  
};
```

```
class Car : public Vehicle {  
    public:  
        // functions  
    private:  
        // made-with (composition)  
    Chassis m_chassis;  
};
```

Aggregation

Aggregation Relationship

What is Aggregation?

- A **Car** “*has a/ uses a*” **Driver**

The **Car** Class is linked to an Object of type **Driver**.

Driver Class is not directly related to the **Car** Class.

- A **Driver** can live out of context of a **Car**.
- A **Driver** must be “contained” in the **Car** object *via a Pointer* to a **Driver** Object.

Aggregation

Aggregation Relationship

Indicative Code example:

➤ *Driver* Inherits from *Base Class Person*:

```
class Driver: public Person {  
    public:  
        // functions  
    private:  
        // data  
        Date    m_licenseExpire;  
        char m_licenseType[LIC_MAX];  
};
```

```
class Car : public Vehicle {  
    public:  
        // functions  
    private:  
        // has-a (aggregation)  
        Driver *m_driver;  
};
```

Inheritance

Inheritance (detailed)

Why Inheritance?

Abstraction for sharing similarities while retaining differences.

Group classes into related families:

- Share common operations and data.

Multiple Inheritance(s) is possible:

- Inherit from multiple Base Classes

```
class Car : public Vehicle,  
           public DMVRegistrable { ... };
```

Promotes code reuse

- Design general Class once.
- Extend implementation(s) through Inheritance.

Inheritance

Inheritance (detailed)

Access Specifier(s)

Inheritance can be **public**, **private**, or **protected**.

- Our focus will be **public** Inheritance.

Public

- Everything that is aware of Base and Derived/Child is also aware that Derived Inherits from Base.

Protected

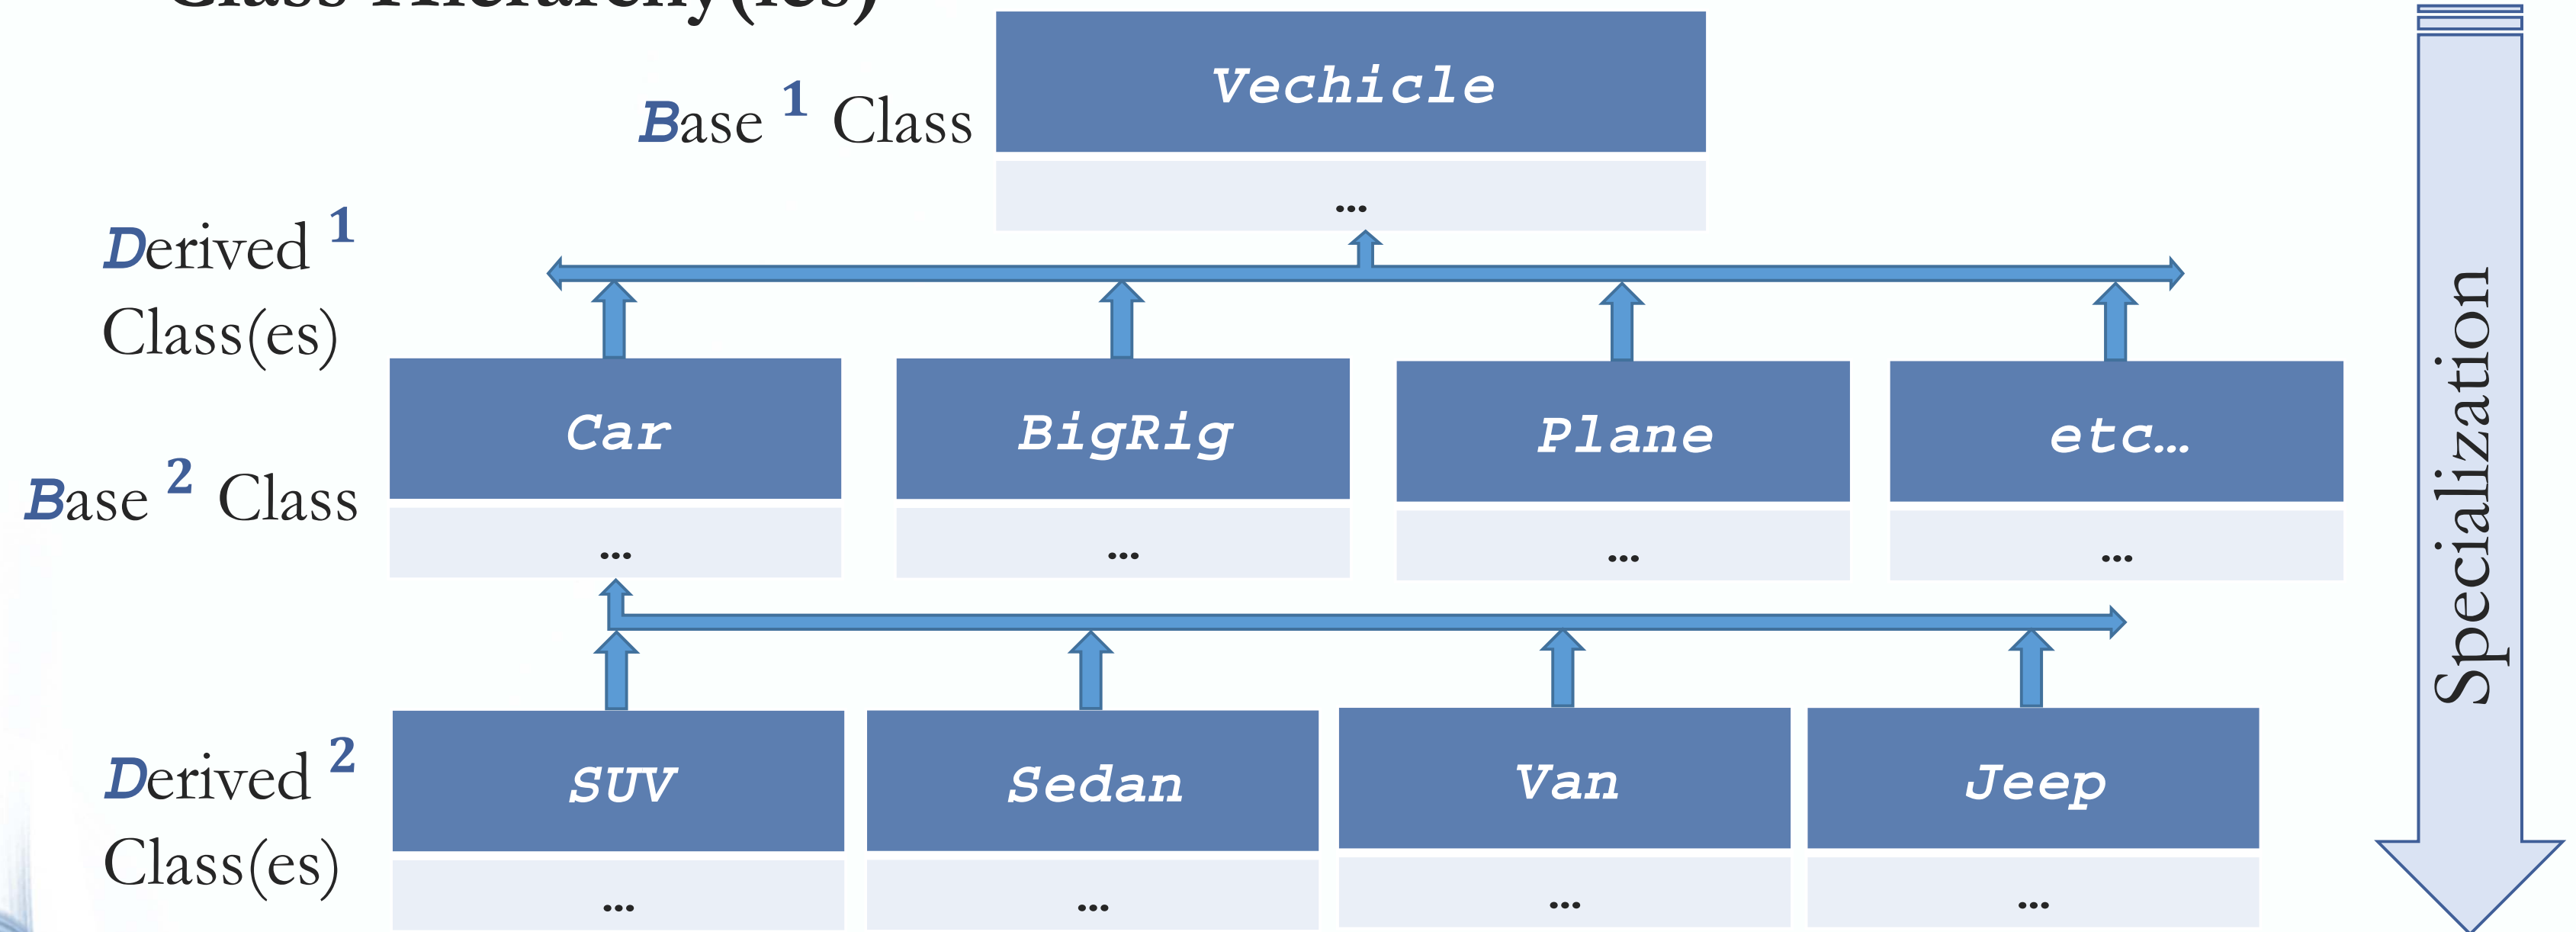

- Only Derived/Child and its own Derived/Children, are aware that they Inherit from Base.

Private

- No one other than Derived/Child is aware of the Inheritance.

Inheritance

Class Hierarchy(ies)

Inheritance

Class Hierarchy(ies)

More general Class (e.g. *Vehicle*) is called:

- Parent Class
- Base Class
- Super-Class

The more specialized Class (e.g. *Car*) is called:

- Derived Class
- Child Class
- Sub-Class

Base
Class(es)

Derived
Class(es)

Specialization

Inheritance

Class Hierarchy(ies)

Parent/Base Class:

- Contains all that is common among its child classes (less specialized).

Example:

A **Vehicle** has members like max speed, weight, etc. because all vehicles have these.

Member Variables and Functions of the Parent/Base Class are Inherited:

- By all of its Child/Derived Classes (Inherited *doesn't always* mean directly accessible!)

Note: Parent/Base Class **protected** & **public** Member Variables:

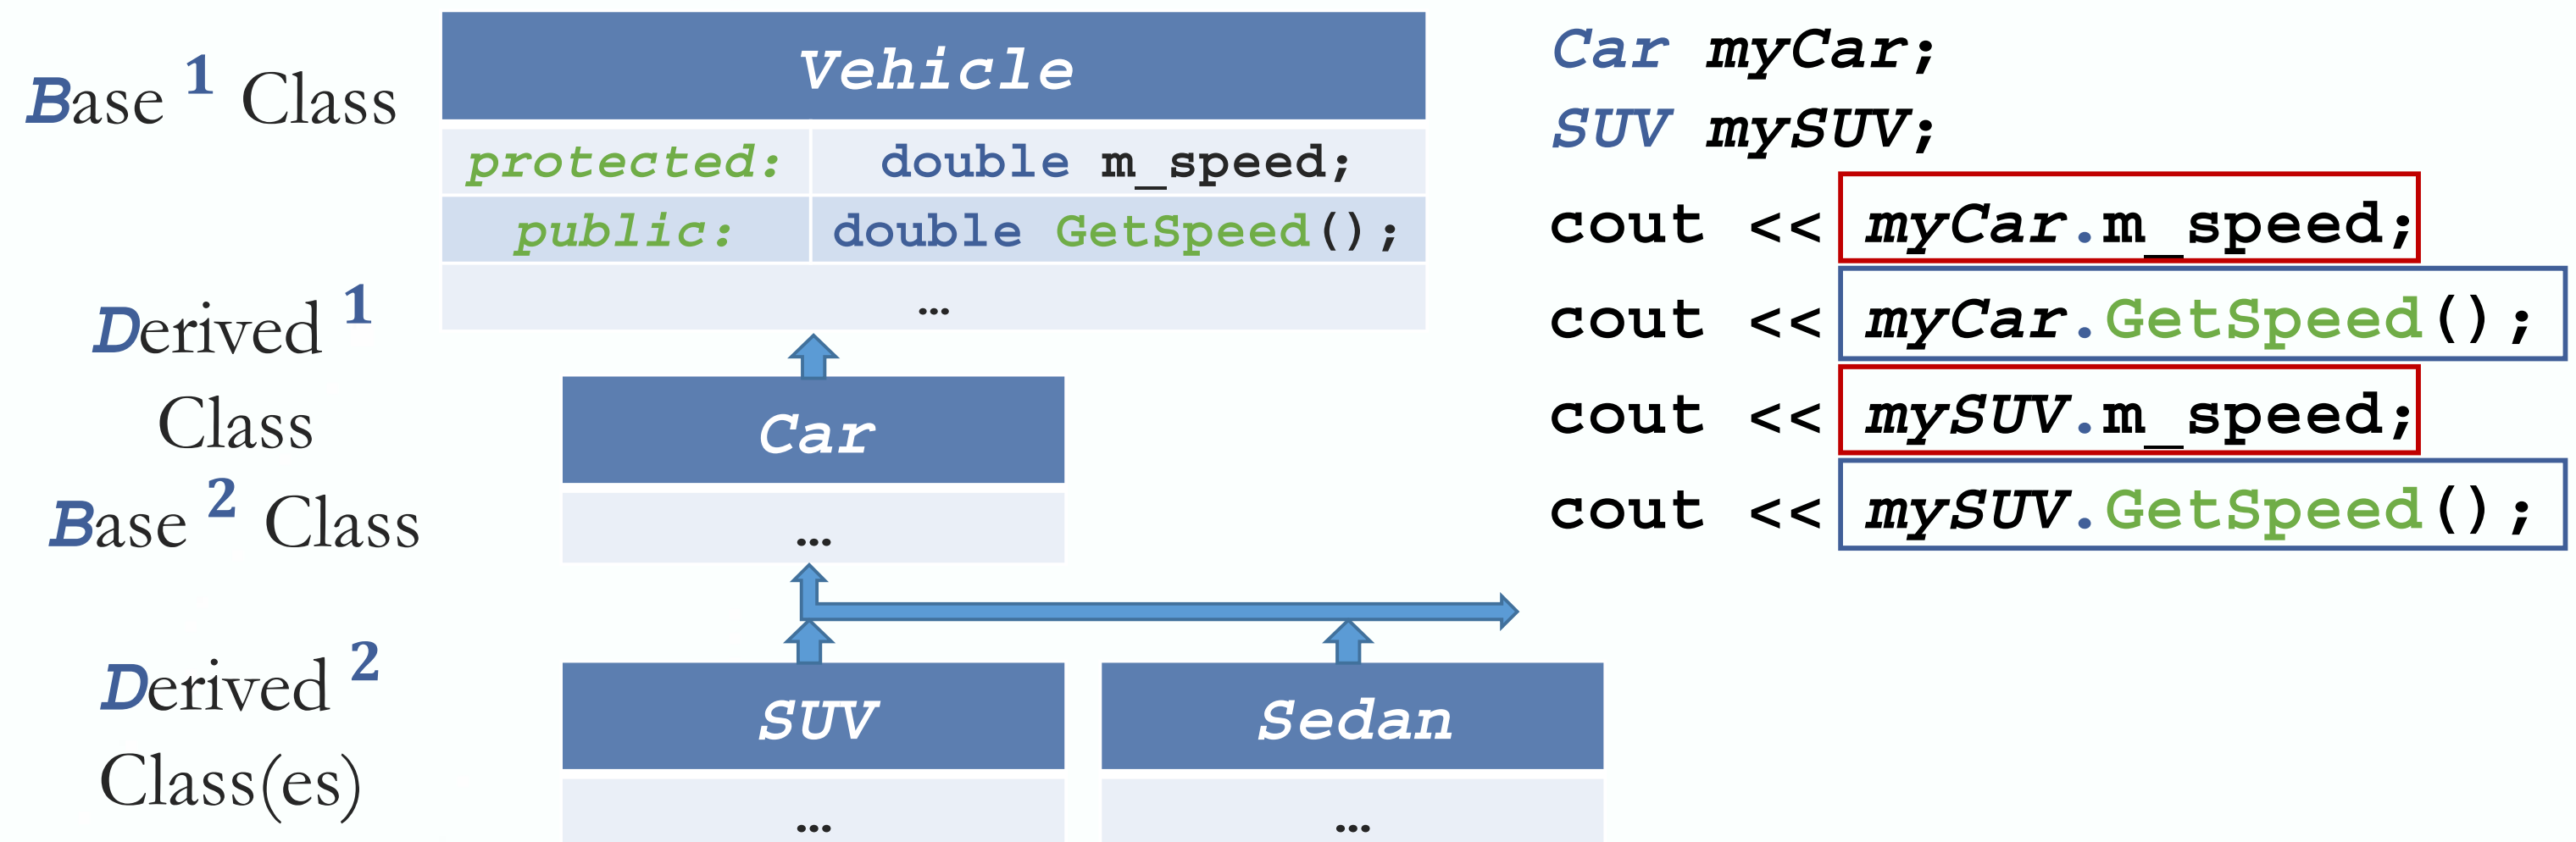

- Directly accessible by Derived/Child Class.

Inheritance

Class Hierarchy(ies)

Derived/Child Class has access to all **public** Methods of Base/Parent Class.

- Can be used on Derived/Child Class Objects!

Inheritance

Class Hierarchy(ies)

Derived/Child Class has access to all **public** Methods of Base/Parent Class.

- Can be used on Derived/Child Class Objects!
- Derived/Child Classes can *Use, Extend, or Replace* the Base/Parent Class behaviors.

Use

Derived/Child Class takes advantage of the Parent Class behaviors exactly as they are:

- E.g. Mutators and Accessors from the Parent Class.

Inheritance

Class Hierarchy(ies)

Derived/Child Class has access to all **public** Methods of Base/Parent Class.

- Can be used on Derived/Child Class Objects!
- Derived/Child Classes can *Use, Extend, or Replace* the Base/Parent Class behaviors.

Extend

Derived/Child Class creates entirely new behaviors:

- E.g. A **RepaintCar()** function for the **Car** Child Class.
Sets of Mutators & Accessors for new Member Variables.

<i>Car</i>
<code>double m_steeringWheelAngle;</code>
<code>double GetSteeringWheelAngle();</code>
...

Own more specialized behaviors

Inheritance

Class Hierarchy(ies)

Derived/Child Class has access to all **public** Methods of Base/Parent Class.

- Can be used on Derived/Child Class Objects!
- Derived/Child Classes can *Use, Extend, or Replace* the Base/Parent Class behaviors.

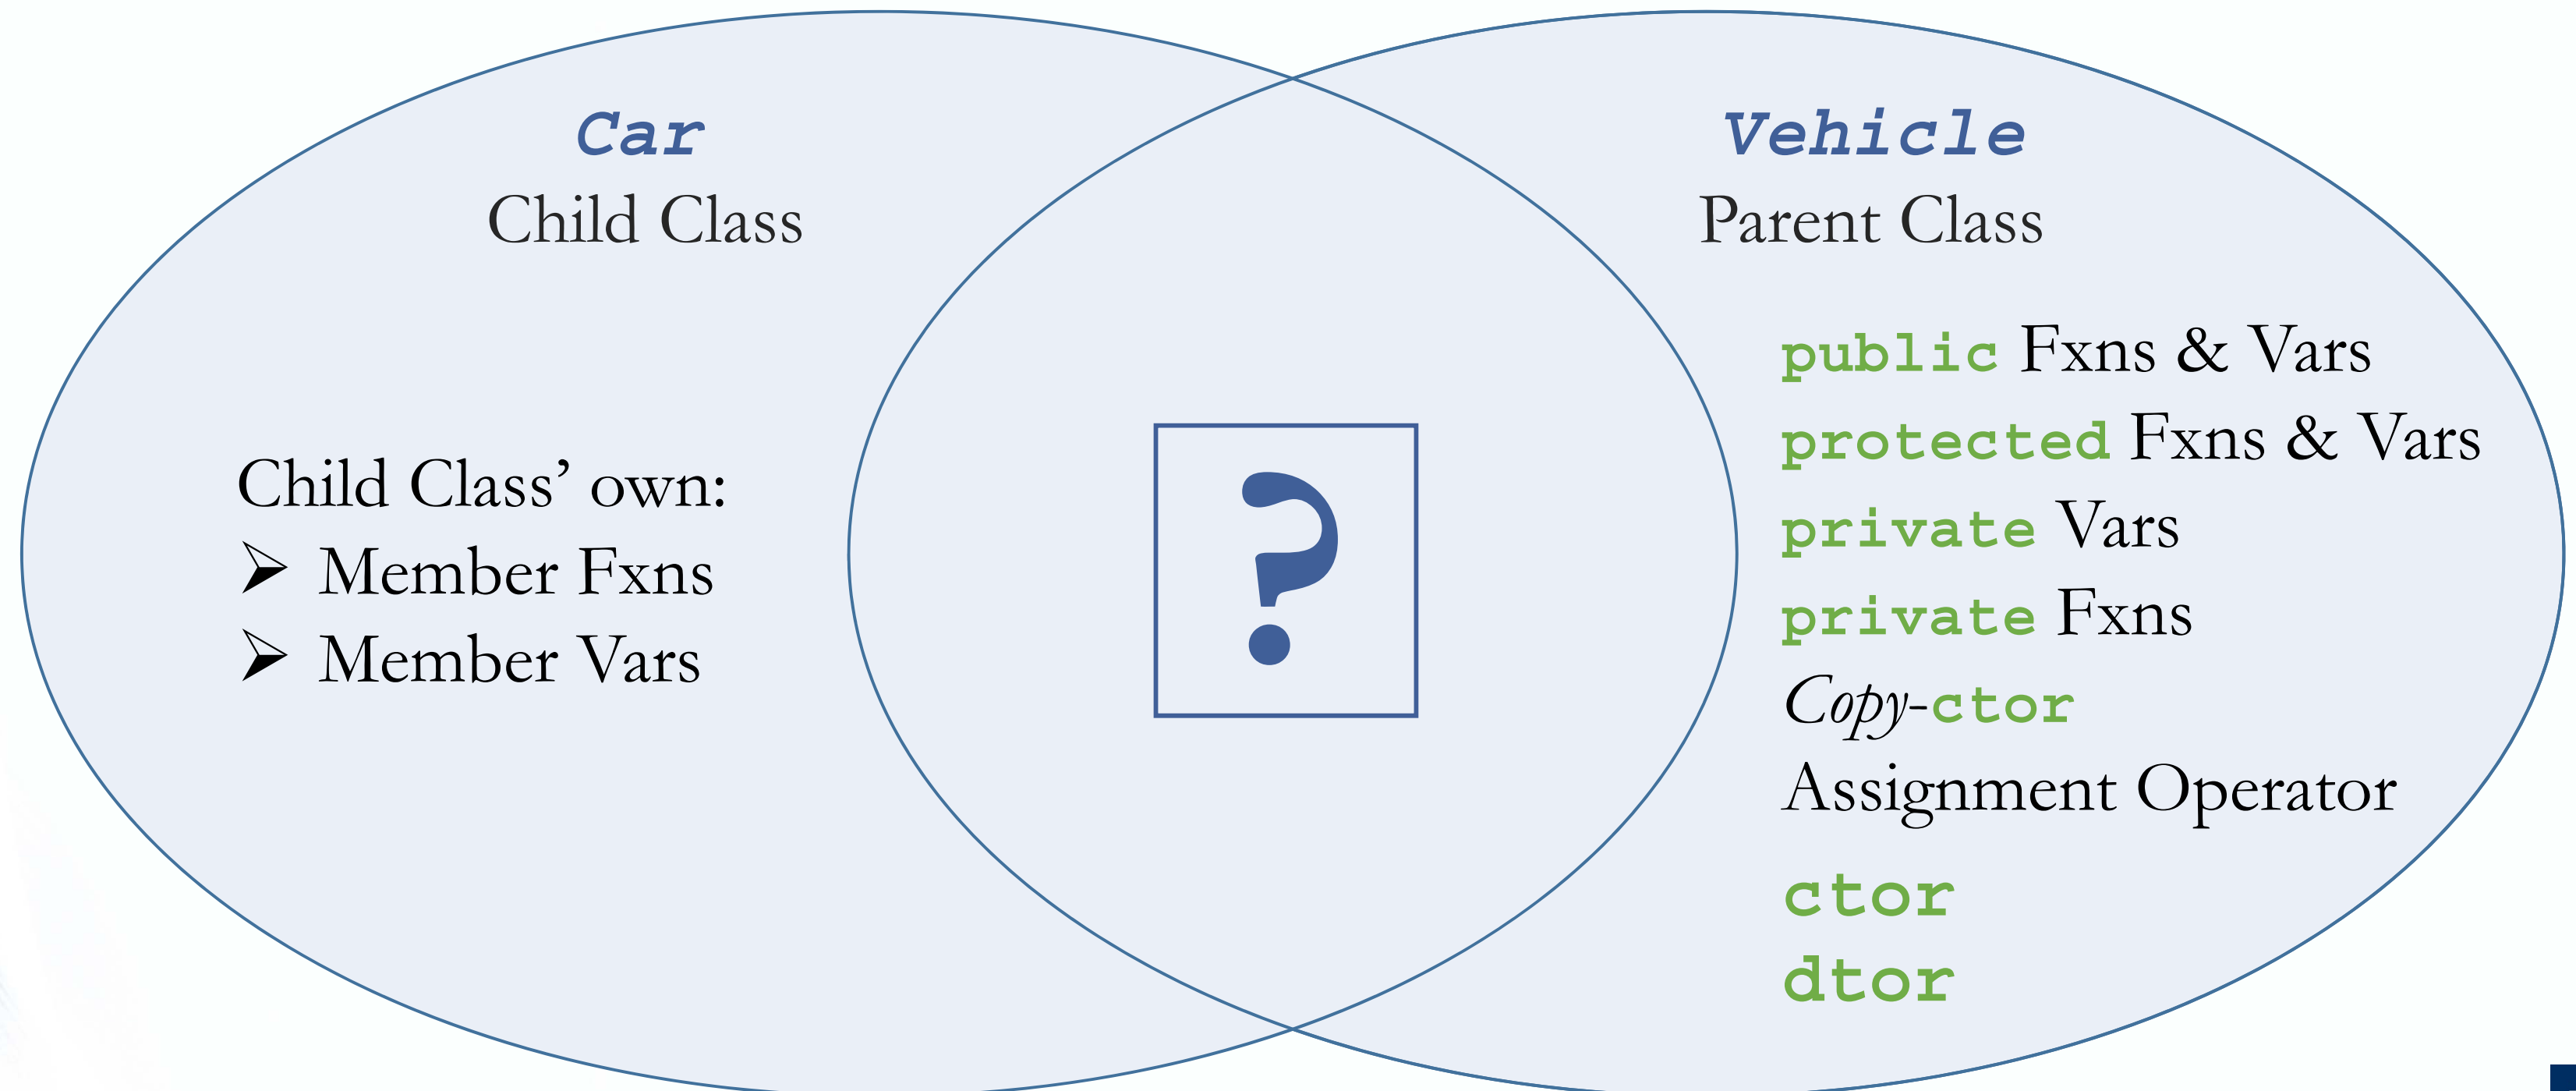

Replace

Derived/Child Class **overrides** Base/Parent Class's behaviors.

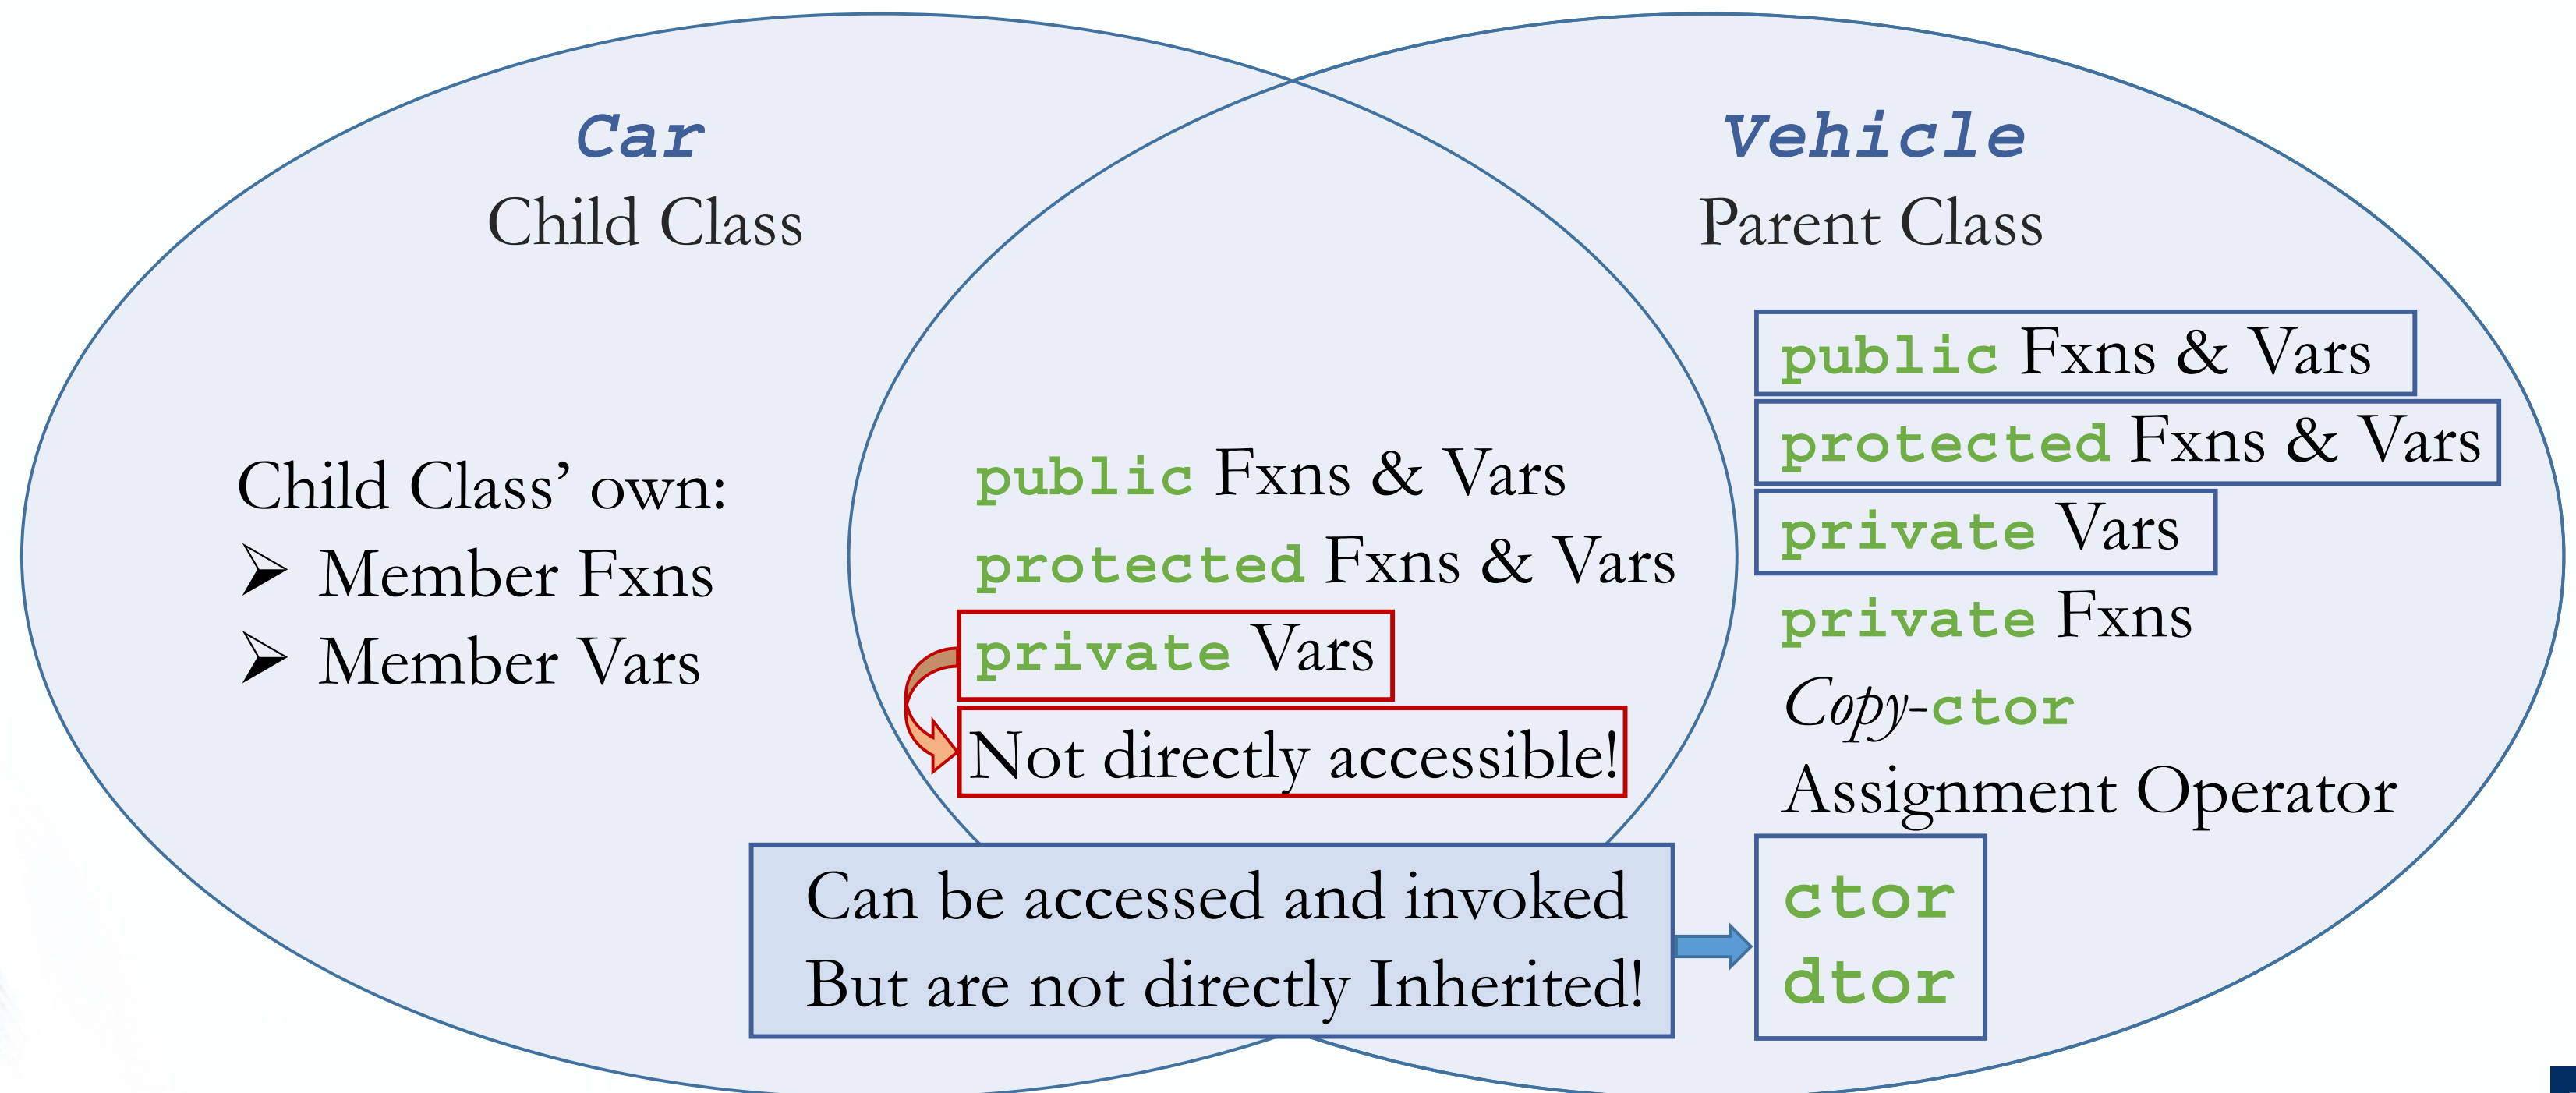

Inheritance

Inherited Member(s)

Inheritance

Inherited Member(s)

Inheritance

Handling Access

Derived/Child Class has access to Base/Parent Class's:

- **protected** Member Variables/Functions.
- **public** Member Variables/Functions (as everything else also does).

No access to Base/Parent Class's **private** Member Variables/Functions:

- Not even through Derived/Child Class' own Member Function.

Remember:

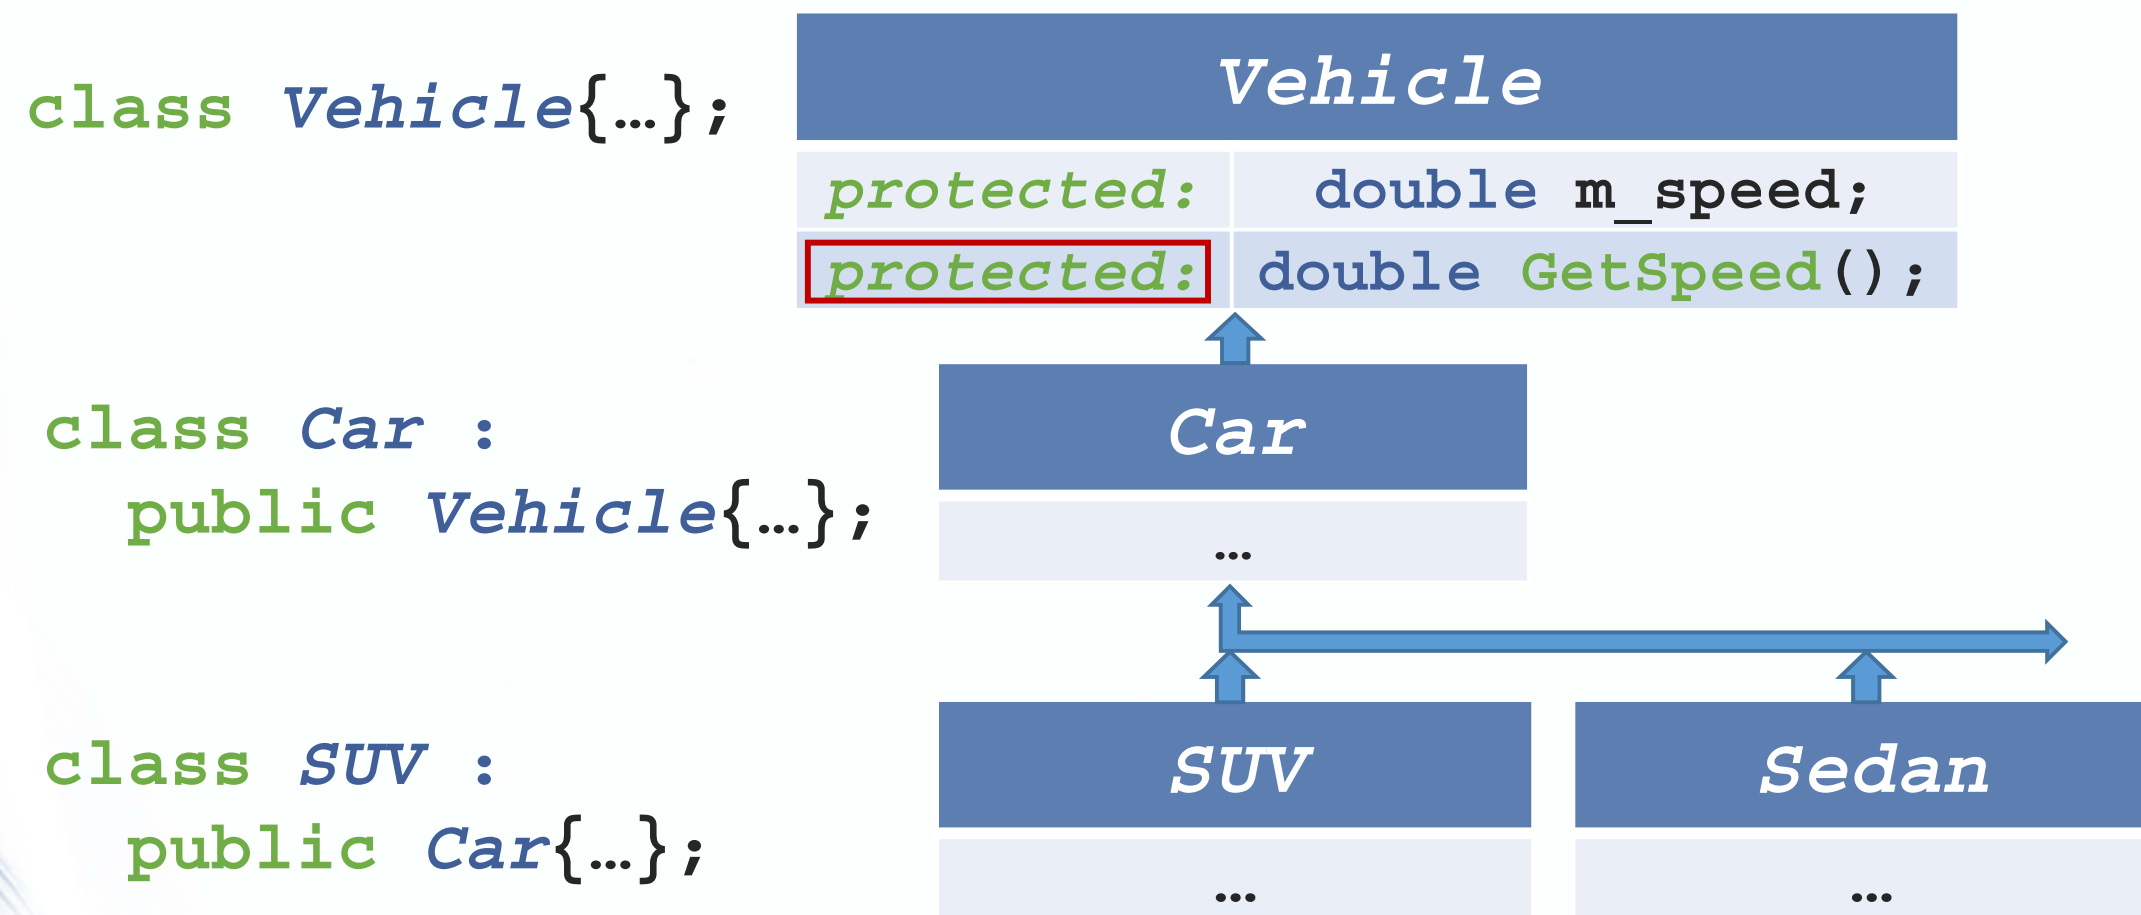

private Member Variables are only directly accessible (“by name”) in Member Functions of their own Class (they one they are defined in).

Inheritance

Handling Access

Only Derived/Child Class has access to Base/Parent Class's:

- **protected** Member Variables/Functions.

```
Car myCar;
```

```
SUV mySUV;
```

```
cout << myCar.GetSpeed();
```

```
cout << mySUV.GetSpeed();
```

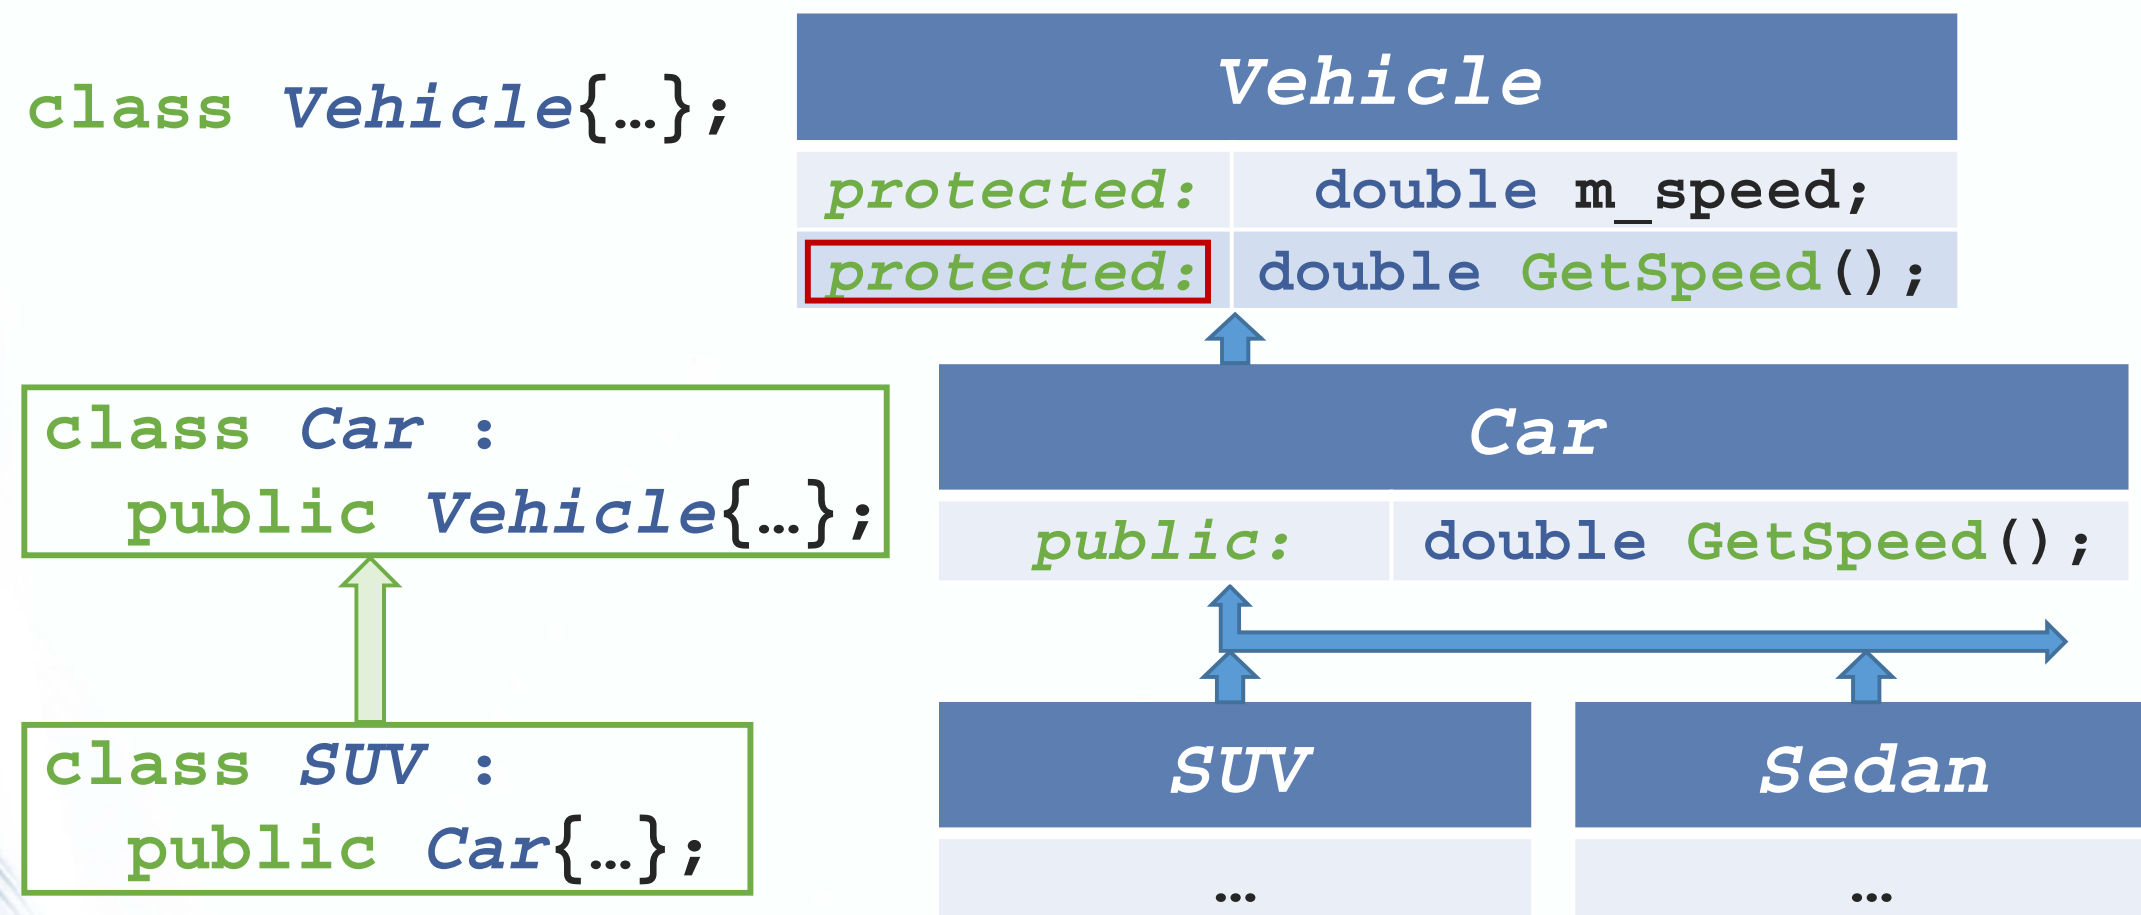

protected specifier does not allow access from outside of Derived/Child Class Functions

Inheritance

Handling Access

Derived/Child Class can override access specification(s) of Base/Parent Class's:

- **protected** Member Variables/Functions.

`Car myCar;`

`SUV mySUV;`

`cout << myCar.GetSpeed();`

`cout << mySUV.GetSpeed();`

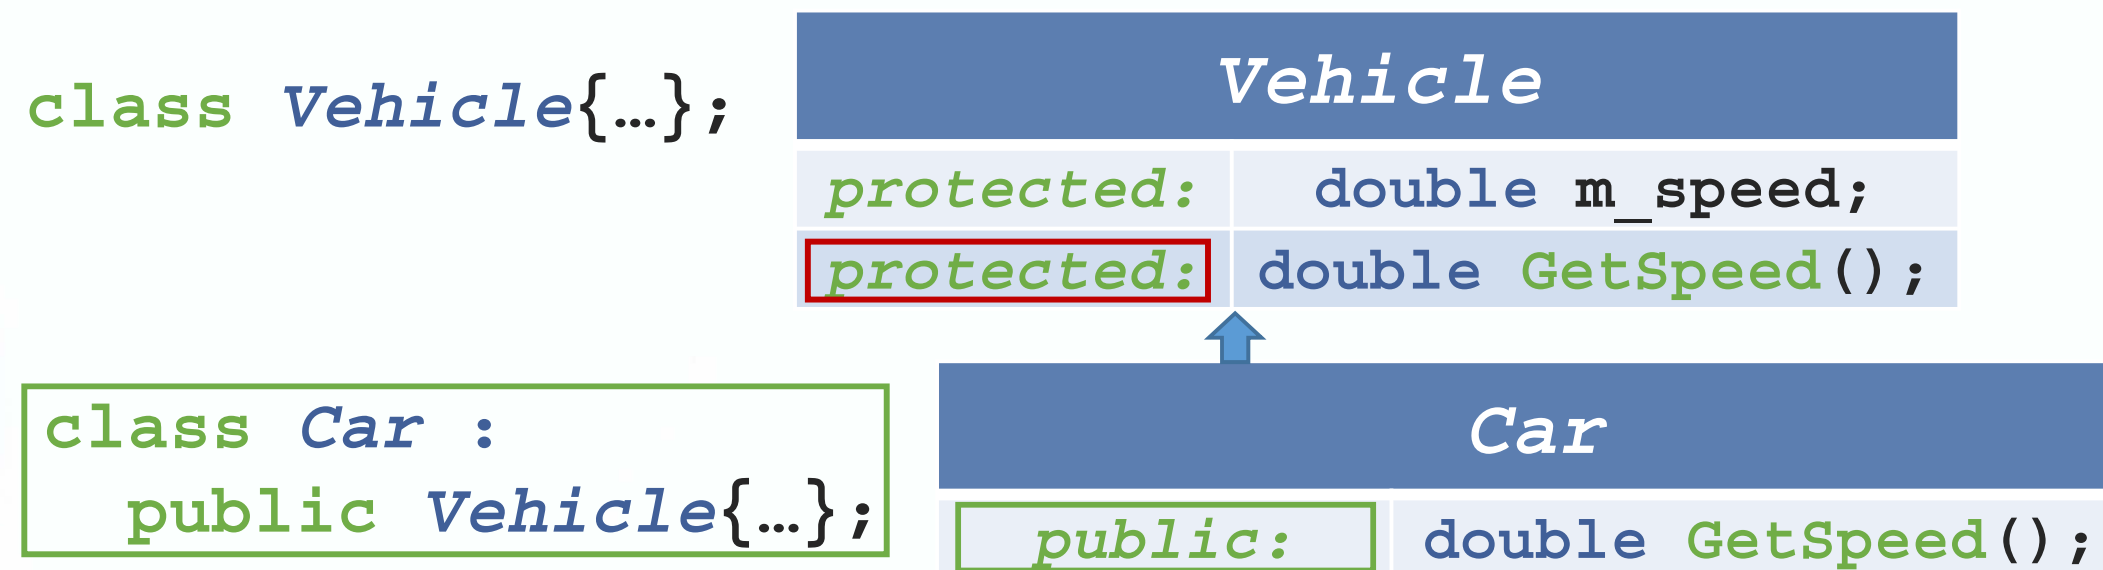

Child Class overrides **protected** access specifier to **public**, Derived Class(es) Inherit new behavior.

Inheritance

Handling Access

Derived/Child Class can override access specification(s) of Base/Parent Class's:

- **protected** Member Variables/Functions.

```
Car myCar;
```

```
SUV mySUV;
```

```
cout << myCar.GetSpeed();
```

Child Class overrides **protected** access specifier to **public**, Derived Class(es) Inherit new behavior.

Note: You can even call the Base Class' method inside your Derived Class' one which overrides it (essentially override only access specification)

```
Vehicle::GetSpeed() { return m_speed; }
```

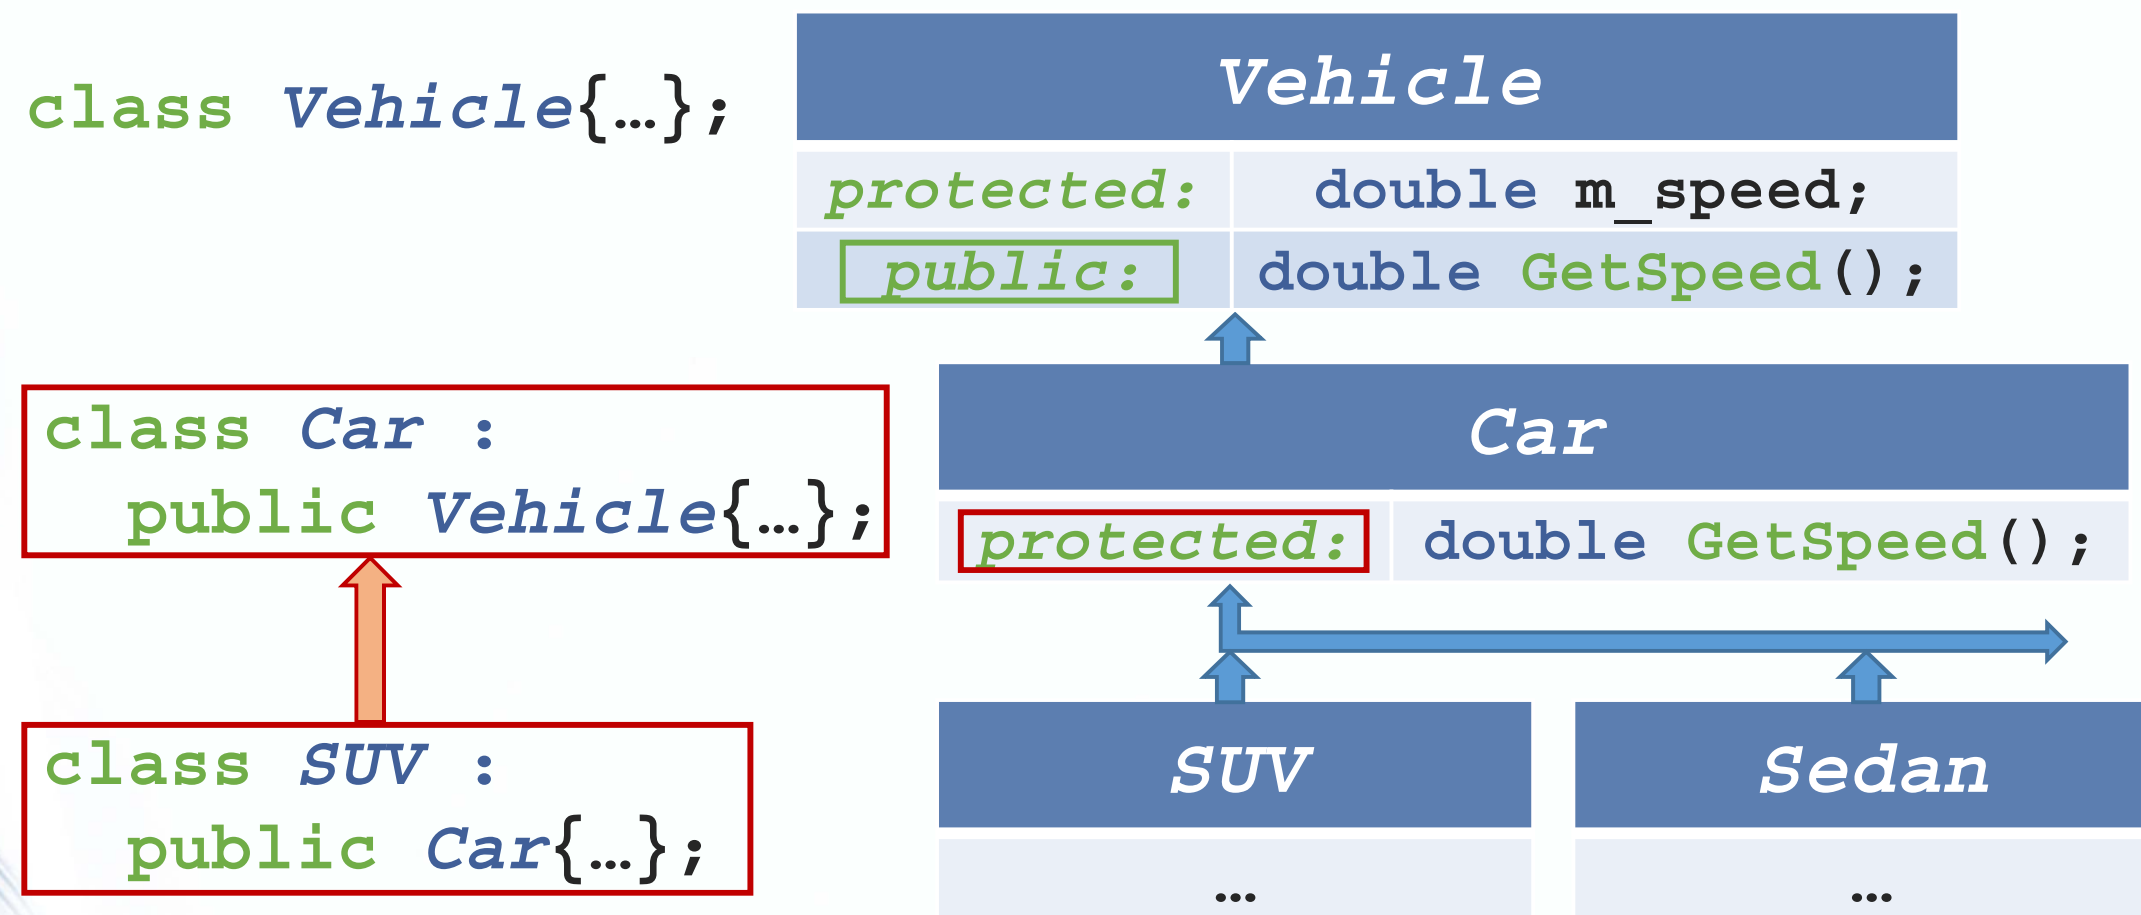

```
Car::GetSpeed() { return GetSpeed(); }
```

Inheritance

Handling Access

Derived/Child Class can override access specification(s) of Base/Parent Class's:

- **protected** Member Variables/Functions.

```
Car myCar;
```

```
SUV mySUV;
```

```
cout << myCar.GetSpeed();
```

```
cout << mySUV.GetSpeed();
```

Child Class overrides **public** access specifier to **protected**, Derived Class(es) Inherit new behavior.

Method Overriding

Overriding

Remember: Interface of a Derived/Child Class:

- *Extends:* Contains declarations for its own new Member Functions.
- *Overrides:* Contains declarations for Inherited Member Functions to be changed.

Implementation of a Derived/Child Class will:

- Define new Member Functions.
- Redefine Inherited Functions *when you Declare them!*

```
class Vehicle {  
    public:  
        int GetMileage() { return m_mileage; }  
    private:  
        int m_mileage;  
};
```

```
class Car {  
    public:  
        int GetMileage();  
};
```

Now that you re-Declared it, you have to Define it!

Method Overriding

Overriding *vs* Overloading

Overriding in a Derived/Child class means *“Redefining what it does”*:

- The same parameters list.
- Essentially “crossing-out & re-writing” what the one-and-same function does!
- Overridden functions share the same signature (because they are one function)!

Overloading a Function means *“Reusing its name”*:

- Using a different parameter(s) list.
- Essentially defining a “new version of” a function (that takes different parameters).
- Overloaded functions must have different signatures!

Method Overriding

Overriding *vs* Overloading

Overriding in a Derived/Child class means *“Redefining what it does”*:

- Overridden functions share the same signature (because they are one function)!

Overloading a Function means *“Reusing its name”*:

- Overloaded functions must have different signatures!

Function *“Signature”*:

- The *unqualified* name of the function.
- The specific sequence of types (names are irrelevant) in parameters list (including order, number, types).
- Signature does NOT include: **return** type (not always – but it’s a later encountered issue), **const** keyword or **&** for parameters.
- Signature DOES include: **cv**-qualifiers (e.g. **const** keyword at the end)

Method Overriding

Overriding *vs* Overloading

Method Overriding (uses exact *same signature*):

- Derived Class Method can modify, add to, or replace Base Class methods.
- **Derived Method** will be called for **Derived Objects**.
- **Base Method** will be called for **Base Objects**.

```
class Animal {  
    public:  
        void Eat() {  
            cout<<"I eat stuff"<<endl;  
        }  
};  
class Lion : public Animal {  
    void Eat() {  
        cout<<"I eat meat"<<endl;  
    }  
};
```

```
int main() {  
    Animal animal;  
    animal.Eat(); // I eat stuff  
    Lion lion;  
    lion.Eat(); // I eat meat  
}
```

Method Overriding

Overriding *vs* Overloading

Method Overloading (uses exact *different signature*):

- A different function (which however carries the same name!)
- Derived/Child Class has access to both functions.

```
class Animal {  
    public:  
    void Eat() {  
        cout<<"I eat stuff"<<endl;  
    }  
};  
  
class Lion : public Animal {  
    public:  
    void Eat(const char* food)  
        cout<<"I ate a "<<food<<endl;  
    }  
};
```

```
int main() {  
    Lion lion;  
    lion.Eat(); // I eat stuff  
    lion.Eat("Steak"); // I ate a Steak  
}
```

Inheritance Rules

Inheritance Exceptions

All “normal” functions in Base/Parent class are Inherited in Derived/Child Class.

Inheritance exceptions are:

➤ Constructor(s) - **ctor**

➤ Destructor(s) - **dtor**

➤ *Copy*-**ctor**

If none is specified for Derived Class, compiler will still generate a “default” one.

➤ Assignment Operator (**=**)

If none is specified for Derived Class, compiler will still generate a “default” one.

Inheritance Rules

Constructor & Destructor in Derived Class(es)

The Base/Parent Class **ctors** are not Inherited in Derived/Child Classes.

- They can however be invoked within Derived/Child Class' **ctor**.

Nothing more is required:

- Base/Parent Class **ctor** must initialize all Base/Parent Class Member Variables.
- These are Inherited by Derived/Child Class!

“First” thing Derived/Child Class **ctor** does is to call Base/Parent Class **ctor**.

Inheritance Rules

Constructor & Destructor in Derived Class(es)

Constructor(s)

- Base/Parent Class **ctor** is called *before* Derived/Child Class **ctor**.

DerivedClass dClass;

BaseClass ();
DerivedClass ();

Destructor

- Derived/Child Class **dtor** is called *before* Base/Parent Class **dtor**.

dClass.**~DerivedClass** ();

~DerivedClass ();
~BaseClass ();

Inheritance Rules

Constructor & Destructor in Derived Class(es)

Sequence of Base-Derived **ctor** & Derived-Base **dtor** calls

Example:

```
class Animal {  
    public:  
        Animal() {cout << "Base constructor"<<endl;}  
        ~Animal() {cout << "Base destructor"<<endl;}  
};  
class Lion : public Animal {  
    public:  
        Lion() {cout << "Derived constructor"<<endl;}  
        ~Lion() {cout << "Derived destructor"<<endl;}  
};
```

```
int main() {  
    Lion lion;  
    return 0;  
}
```

Output:

```
Base constructor  
Derived constructor  
Derived destructor  
Base destructor
```

Inheritance Rules

Parametrized Constructor in Derived Class(es)

Calling the Base **ctor** from a Derived **ctor** explicitly

Example:

```
class Animal {  
    public:  
        Animal(const char* name) {  
            strcpy(m_name, name);  
            cout<<m_name<<endl;  
        }  
    protected:  
        char m_name[MAXNAME];  
};  
class Lion : public Animal {  
    public:  
        Lion(const char* name) : Animal(name) {  
        }  
};
```

```
int main() {  
    Lion lion("King");  
    return 0;  
}
```

Output:
King

Note: Initializer-list is the only way that allows calling the Base **ctor** from a Derived **ctor**.

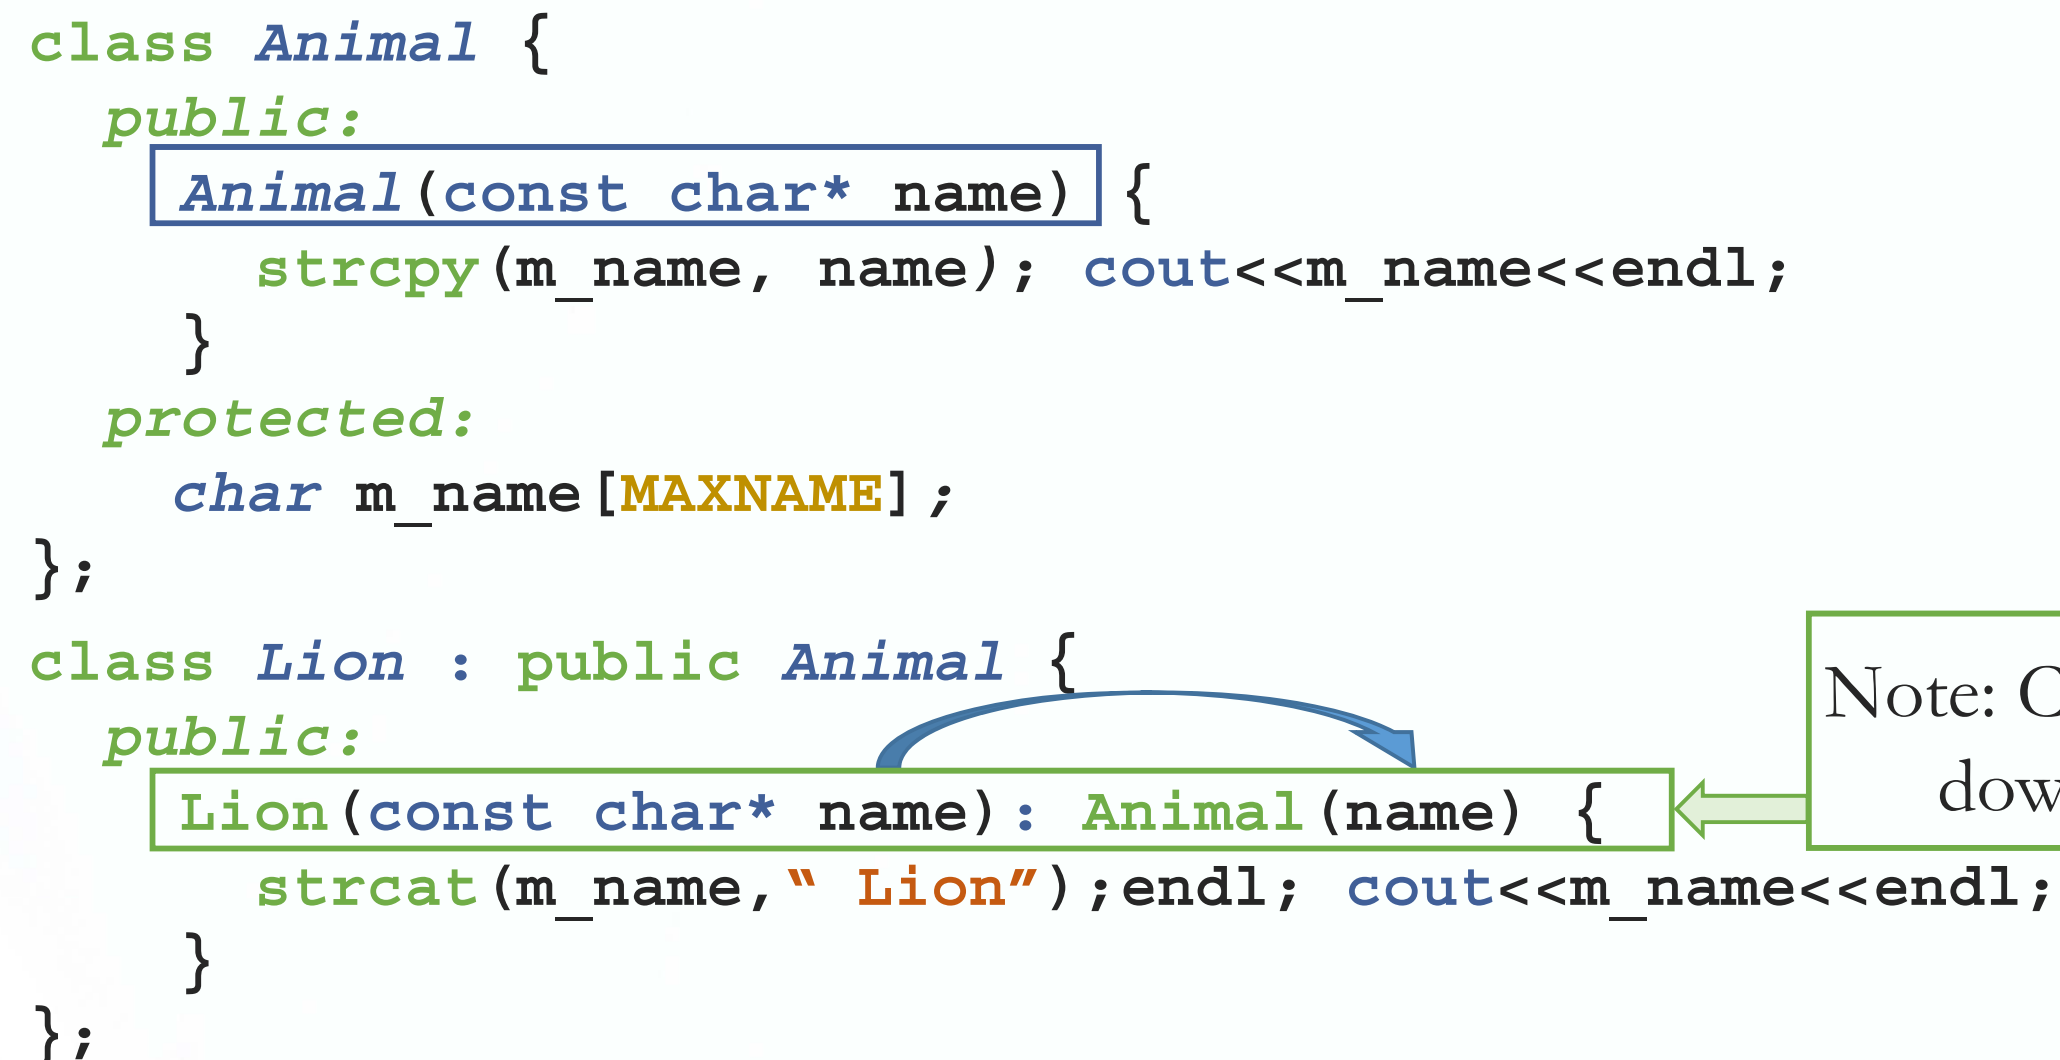

Inheritance Rules

Parametrized Constructor in Derived Class(es)

Calling the Base **ctor** from a Derived **ctor** explicitly

Example:

```
class Animal {  
    public:  
        Animal(const char* name) {  
            strcpy(m_name, name); cout<<m_name<<endl;  
        }  
    protected:  
        char m_name[MAXNAME];  
};  
  
class Lion : public Animal {  
    public:  
        Lion(const char* name) : Animal(name) {  
            strcat(m_name, " Lion"); endl; cout<<m_name<<endl;  
        }  
};
```

```
int main() {  
    Lion lion("King");  
    return 0;  
}
```

Output:
King
King Lion

Note: Calls Parametrized Base **ctor** by passing down argument from the Derived **ctor**.

CS-202

Time for Questions !
